Site visit to Sao Chaliang
Pha Taem National Park
Ubon Ratchathani, Thailand
May 6, 2018
Sao Chaliang is one sculptures of the nature. It has been produced by erosion process that taking place on the sandstone beds. The rocks were deposited by fluvial process in Early Cretaceous (125 - 110 Ma). After the sandstone had been buried for millions of year, the rock sequences were uplifted by geotectonic process. As the results, cracks on the rocks have been formed as a network of joint sets. Over millions of year, after process of erosion caused by water, wind and sunlight that had slowly broken and eroded away at the cracks, it made the cracks bigger. Joints became chasms and pillars began to form as we can see in today.
